Department of Computer Science

Aalto University

visiting in Sapienza University of Rome fall 2016

spectral graph theory

## spectral graph theory

#### objective:

- view the adjacency (or related) matrix of a graph with a linear algebra lens
- identify connections between spectral properties of such a matrix and structural properties of the graph
  - connectivity
  - bipartiteness
  - cuts
  - ...
- spectral properties = eigenvalues and eigenvectors
- in other words, what does the eigenvalues and eigenvectors of the adjacency (or related) matrix tell us about the graph?

- consider a real  $n \times n$  matrix A, i.e.,  $A \in \mathbb{R}^{n \times n}$
- $\lambda \in \mathbb{C}$  is an eigenvalue of A if there exists  $\mathbf{x} \in \mathbb{C}^n$ ,  $\mathbf{x} \neq \mathbf{0}$  such that

$$A\mathbf{x} = \lambda \mathbf{x}$$

- such a vector x is called eigenvector of λ
- alternatively,

$$(A - \lambda I) \mathbf{x} = \mathbf{0}$$
 or  $det(A - \lambda I) = 0$ 

it follows that A has n eigenvalues
 (possibly complex and possibly with multiplicity > 1)

- consider a real and symmetric n × n matrix A
   (e.g., the adjacency matrix of an undirected graph)
- then
- all eigenvalues of A are real
- eigenvectors of different eigenvalues are orthogonal i.e., if  $\mathbf{x}_1$  an eigenvector of  $\lambda_1$  and  $\mathbf{x}_2$  an eigenvector of  $\lambda_2$  then  $\lambda_1 \neq \lambda_2$  implies  $\mathbf{x}_1 \perp \mathbf{x}_2$  (or  $\mathbf{x}_1^T \mathbf{x}_2 = 0$ )
- A is positive semi-definite if  $\mathbf{x}^T A \mathbf{x} > 0$  for all  $\mathbf{x} \in \mathbb{R}^n$
- a symmetric positive semi-definite real matrix has real and non negative eigenvalues

- consider a real and symmetric n × n matrix A
- the eigenvalues  $\lambda_1, \ldots, \lambda_n$  of A can be ordered

$$\lambda_1 \leq \ldots \leq \lambda_n$$

• theorem [variational characterization of eigenvalues]

$$\lambda_{n} = \max_{\mathbf{x} \neq \mathbf{0}} \frac{\mathbf{x}^{T} A \mathbf{x}}{\mathbf{x}^{T} \mathbf{x}}$$

$$\lambda_{1} = \min_{\mathbf{x} \neq \mathbf{0}} \frac{\mathbf{x}^{T} A \mathbf{x}}{\mathbf{x}^{T} \mathbf{x}}$$

$$\lambda_{2} = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^{T} \mathbf{x}_{1} = \mathbf{0}}} \frac{\mathbf{x}^{T} A \mathbf{x}}{\mathbf{x}^{T} \mathbf{x}} \quad \text{and "so on" for the other eigenvalues}$$

very useful way to think about eigenvalues

· the inverse holds, i.e.,

$$\lambda_1 = \min_{\mathbf{x} \neq \mathbf{0}} \frac{\mathbf{x}^T A \mathbf{x}}{\mathbf{x}^T \mathbf{x}} = \min_{\mathbf{x} \neq \mathbf{0}} \frac{\sum_{ij} A_{ij} x_i x_j}{\sum_i x_i^2}$$

- and if  $\mathbf{x}$  is an optimal vector, then  $\mathbf{x}$  is eigenvector of  $\lambda_1$
- similarly

$$\lambda_2 = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = 0}} \frac{\mathbf{x}^T A \mathbf{x}}{\mathbf{x}^T \mathbf{x}} = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = 0}} \frac{\sum_{ij} A_{ij} X_i X_j}{\sum_i X_i^2}$$

• and if  $\mathbf{x}$  is an optimal vector, then  $\mathbf{x}$  is eigenvector of  $\lambda_2$ 

## spectral graph analysis

- apply the eigenvalue characterization for graphs
- question: which matrix to consider?
  - the adjacency matrix A of the graph
  - some matrix B so that  $\mathbf{x}^T B \mathbf{x}$  is related to a structural property of the graph
- consider G = (V, E) an undirected and d-regular graph (regular graph is used wlog for simplicity of expositions)
- let A be the adjacency matrix of G:
- define the laplacian matrix of G as

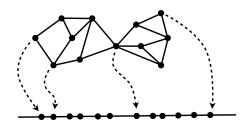

$$L = I - \frac{1}{d}A \qquad \text{or} \qquad L_{ij} = \begin{cases} 1 & \text{if } i = j \\ -1/d & \text{if } (i,j) \in E, i \neq j \\ 0 & \text{if } (i,j) \notin E, i \neq j \end{cases}$$

## spectral graph analysis

• for the laplacian matrix  $L = I - \frac{1}{d} A$  it is

$$\mathbf{x}^T L \mathbf{x} = \frac{1}{d} \sum_{(u,v) \in E} |x_u - x_v|^2$$

- here, x<sub>u</sub> is the coordinate of the eigenvector x that corresponds to vertex u ∈ V
- eigenvector x is seen as a one-dimensional embedding
- i.e., mapping the vertices of the graph onto the real line

## spectral graph analysis

#### high-level remark

- many graph problems can be modeled as mapping of vertices to a discrete space
  - e.g., a cut is a mapping of vertices to  $\{0, 1\}$
- we aim to find a spectral formulation so that an eigenvector x is a relaxation of the discrete graph problem
  - i.e., optimizes the same objective but without the integrality constraint

## the smallest eigenvalue

apply the eigenvalue characterization theorem for L

• what is  $\lambda_1$ ?

$$\lambda_1 = \min_{\mathbf{x} \neq \mathbf{0}} \frac{\mathbf{x}^T L \mathbf{x}}{\mathbf{x}^T \mathbf{x}} = \min_{\mathbf{x} \neq \mathbf{0}} \frac{\sum_{(u,v) \in E} |x_u - x_v|^2}{d \sum_{u \in V} x_u^2}$$

- observe that  $\lambda_1 \geq 0$
- can it be  $\lambda_1 = 0$ ?
- yes: take x to be the constant vector

## the second smallest eigenvalue

apply the eigenvalue characterization theorem for L

• what is  $\lambda_2$ ?

$$\lambda_2 = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = 0}} \frac{\mathbf{x}^T L \mathbf{x}}{\mathbf{x}^T \mathbf{x}} = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = 0}} \frac{\sum_{(u, v) \in E} |x_u - x_v|^2}{d \sum_{u \in V} x_u^2}$$

- can it be  $\lambda_2 = 0$ ?
- λ<sub>2</sub> = 0 if and only if the graph is disconnected map the vertices of each connected component to a different constant

## the k-th smallest eigenvalue

• alternative characterization for  $\lambda_k$ 

$$\lambda_k = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x} \in \mathbb{S} \\ \mathbb{S}: k\text{-dim}}} \max \frac{\sum_{(u,v) \in E} |x_u - x_v|^2}{d \sum_{u \in V} x_u^2}$$

 λ<sub>k</sub> = 0 if and only if the graph has at least k connected components

## the largest eigenvalue

what about λ<sub>n</sub>?

$$\lambda_n = \max_{\mathbf{x} \neq \mathbf{0}} \frac{\mathbf{x}^T L \mathbf{x}}{\mathbf{x}^T \mathbf{x}} = \max_{\mathbf{x} \neq \mathbf{0}} \frac{\sum_{(u,v) \in E} |x_u - x_v|^2}{d \sum_{u \in V} x_u^2}$$

- consider a boolean version of this problem
- restrict mapping to  $\{-1, +1\}$

$$\lambda_n \ge \max_{\mathbf{x} \in \{-1, +1\}^n} \frac{\sum_{(u, v) \in E} |x_u - x_v|^2}{d \sum_{u \in V} x_u^2}$$

## the largest eigenvalue

mapping of vertices to {-1,+1} corresponds to a cut S
 then

$$\lambda_{n} \geq \max_{\mathbf{x} \in \{-1,+1\}^{n}} \frac{\sum_{(u,v) \in E} |x_{u} - x_{v}|^{2}}{d \sum_{u \in V} x_{u}^{2}}$$

$$= \max_{S \subseteq V} \frac{4 E(S, V \setminus S)}{d n}$$

$$= \max_{S \subseteq V} \frac{4 E(S, V \setminus S)}{2 |E|}$$

$$= \frac{2 \max_{U \in S} \operatorname{cut}(G)}{|E|}$$

it follows that if G bipartite then λ<sub>n</sub> ≥ 2
 (because if G bipartite exists S that cuts all edges)

## the largest eigenvalue

on the other hand

$$\lambda_{n} = \max_{\mathbf{x} \neq \mathbf{0}} \frac{\sum_{(u,v) \in E} |x_{u} - x_{v}|^{2}}{d \sum_{u \in V} x_{u}^{2}}$$

$$= \max_{\mathbf{x} \neq \mathbf{0}} \frac{2d \sum_{u \in V} x_{u}^{2} - \sum_{(u,v) \in E} (x_{u} + x_{v})^{2}}{d \sum_{u \in V} x_{u}^{2}}$$

$$= 2 - \min_{\mathbf{x} \neq \mathbf{0}} \frac{\sum_{(u,v) \in E} (x_{u} + x_{v})^{2}}{d \sum_{u \in V} x_{u}^{2}}$$

- first note that  $\lambda_n \leq 2$
- $\lambda_n = 2$  iff there is **x** s.t.  $x_u = -x_v$  for all  $(u, v) \in E$
- $\lambda_n = 2$  iff G has a bipartite connected component

## summary so far

#### eigenvalues and structural properties of G:

- $\lambda_2 = 0$  iff *G* is disconnected
- $\lambda_k = 0$  iff G has at least k connected components
- $\lambda_n = 2$  iff G has a bipartite connected component

#### robustness

- how robust are these results?
- for instance, what if  $\lambda_2 = \epsilon$  ?

is the graph G almost disconnected?

i.e., does it have small cuts?

• or, what if  $\lambda_n = 2 - \epsilon$ ?

does it have a component that is "close" to bipartite?

## the second eigenvalue

$$\lambda_2 = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = \mathbf{0}}} \frac{\sum_{(u, v) \in E} (x_u - x_v)^2}{d \sum_{u \in V} x_u^2} = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = \mathbf{0}}} \frac{\sum_{(u, v) \in E} (x_u - x_v)^2}{\frac{d}{n} \sum_{(u, v) \in V^2} (x_u - x_v)^2}$$

where  $V^2$  is the set of ordered pairs of vertices

#### why?

$$\sum_{(u,v)\in V^2} (x_u - x_v)^2 = n \sum_v x_v^2 - 2 \sum_{u,v} x_u x_v = n \sum_v x_v^2 - 2 \left(\sum_u x_u\right)^2$$
and 
$$\sum_u x_u = 0 \text{ since } \mathbf{x}^T \mathbf{x}_1 = 0$$

## the second eigenvalue

$$\lambda_2 = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = \mathbf{0}}} \frac{\sum_{(u,v) \in E} (x_u - x_v)^2}{\frac{d}{n} \sum_{(u,v) \in V^2} (x_u - x_v)^2} = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \mathbf{x}^T \mathbf{x}_1 = \mathbf{0}}} \frac{n}{d} \frac{\mathbb{E}_{(u,v) \in E} [(x_u - x_v)^2]}{\mathbb{E}_{(u,v) \in V^2} [(x_u - x_v)^2]}$$

consider again discrete version of the problem,  $x_u \in \{0, 1\}$ 

$$\min_{\substack{\mathbf{x} \neq \{0,1\}^n \\ \mathbf{x} \text{ non const}}} \frac{n}{d} \frac{\mathbb{E}_{(u,v) \in E}[(x_u - x_v)^2]}{\mathbb{E}_{(u,v) \in V^2}[(x_u - x_v)^2]} = \min_{S \subseteq V} \frac{n}{d} \frac{E(S, \overline{S})}{|S||\overline{S}|} = \text{usc}(G)$$

usc(G): uniform sparsest cut of G

## uniform sparsest cut

it can be shown that

$$\lambda_2 \leq \mathsf{usc}(G) \leq \sqrt{8\lambda_2}$$

- the first inequality holds the by definition of relaxation
- second inequality is constructive :
- if **x** is an eigenvector of  $\lambda_2$

then there is some  $t \in V$  such that

the cut 
$$(S, V \setminus S) = (\{u \in V \mid x_u \le x_t\}, \{u \in V \mid x_u > x_t\})$$

has cost  $\operatorname{usc}(S) \leq \sqrt{8\lambda_2}$ 

#### conductance

- conductance : another measure for cuts
- the conductance of a set  $S \subseteq V$  is defined as

$$\phi(S) = \frac{E(S, V \setminus S)}{d|S|}$$

- expresses the probability to "move out" of S by following a random edge from S
- we are interested in sets of small conductance
- the conductance of the graph G is defined as

$$\phi(G) = \min_{\substack{S \subseteq V \\ 0 \le S \le |V|/2}} \phi(S)$$

## Cheeger's inequality

Cheeger's inequality:

$$\frac{\lambda_2}{2} \le \frac{\mathsf{usc}(G)}{2} \le \phi(G) \le \sqrt{2\lambda_2}$$

 $\Rightarrow$  conductance is small if and only if  $\lambda_2$  is small

- the two leftmost inequalities are "easy" to show
- the first follows by the definition of relaxation
- the second follows by

$$\frac{\mathsf{usc}(S)}{2} = \frac{n}{2d} \frac{E(S, V \setminus S)}{|S||V \setminus S|} \le \frac{E(S, V \setminus S)}{d|S|} = \phi(S)$$

since 
$$|V \setminus S| \ge n/2$$

## Cheeger's inequality

$$\frac{\lambda_2}{2} \le \frac{\mathsf{usc}(G)}{2} \le \phi(G) \le \sqrt{2\lambda_2}$$

- the rightmost inequality is the "difficult" to show
- proof sketch (three steps):
- 1. consider a vector  $\mathbf{y} \geq \mathbf{0}$
- we can find a set S ⊆ { $v \in V \mid y_v > 0$ } such that

$$\phi(S) \le \frac{\sum_{(u,v)\in E} |y_u - y_v|}{d\sum_{u\in V} |y_u|}$$
 (no squares)

- pick random  $t \in [0, \max_{v} y_{v}]$  and define  $S = \{v \mid y_{v} \ge t\}$
- − then  $\phi(S) \le r.h.s$  on expectation
- thus, there is some t that the property holds

## Cheeger's inequality

$$\frac{\lambda_2}{2} \le \frac{\mathsf{usc}(G)}{2} \le \phi(G) \le \sqrt{2\lambda_2}$$

- proof sketch (three steps):
- 2. given a vector **x** we can find another vector **y** such that

$$\frac{\sum_{(u,v)\in E} |y_u - y_v|}{d\sum_{u\in V} |y_u|} \le \sqrt{2\frac{\sum_{(u,v)\in E} |x_u - x_v|^2}{d\sum_{u\in V} |x_u|^2}}$$

and 
$$|\{v \mid y_v > 0\}| \le \frac{n}{2}$$

- proof of this claim is constructive; uses Cauchy-Schwarz
- 3. take x to be the eigenvector of  $\lambda_2$

## generalization to non-regular graphs

- G = (V, E) is undirected and non-regular
- let  $d_u$  be the degree of vertex u
- define D to be a diagonal matrix whose u-th diagonal element is du
- the normalized laplacian matrix of G is defined

$$L = I - D^{-1/2} A D^{-1/2}$$

or

$$L_{uv} = \begin{cases} 1 & \text{if } u = v \\ -1/\sqrt{d_u d_v} & \text{if } (u, v) \in E, u \neq v \\ 0 & \text{if } (u, v) \notin E, u \neq v \end{cases}$$

## generalization to non-regular graphs

• with the *normalized laplacian* the eigenvalue expressions become (e.g.,  $\lambda_2$ )

$$\lambda_2 = \min_{\substack{\mathbf{x} \neq \mathbf{0} \\ \langle \mathbf{x}, \mathbf{x}_1 \rangle_D = \mathbf{0}}} \frac{\sum_{(u, v) \in E} (x_u - x_v)^2}{\sum_{u \in V} d_u x_u^2}$$

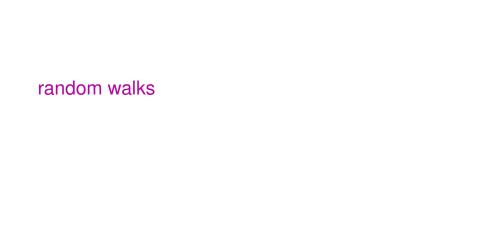

where we use weighted inner product

$$\langle \mathbf{x}, \mathbf{y} \rangle_D = \sum_{u \in V} d_u x_u y_u$$

## summary so far

#### eigenvalues and structural properties of G:

- $\lambda_2 = 0$  iff G is disconnected
- $\lambda_k = 0$  iff G has at least k connected components
- $\lambda_n = 2$  iff G has a bipartite connected component
- small  $\lambda_2$  iff G is "almost" disconnected (small conductance)

#### random walks

- consider random walk on the graph G by following edges
- from vertex *i* move to vertex *j* with prob.  $1/d_i$  if  $(i,j) \in E$
- $\mathbf{p}_{i}^{(t)}$  probability of being at vertex i at time t
- process is described by equation  $\mathbf{p}^{(t+1)} = \mathbf{p}^{(t)}P$ , where  $P = D^{-1}A$  is row-stochastic
- process converges to stationary distribution  $\pi = \pi P$  (under certain irreducibility conditions)
- for undirected and connected graphs

$$\pi_i = \frac{d_i}{2m}$$
 (stationary distribution  $\sim$  degree)

## random walks — useful concepts

- hitting time H(i, j): expected number of steps before visiting vertex j, starting from i
- commute time  $\kappa(i,j)$ : expected number of steps before visiting j and i again, starting at i:  $\kappa(i,j) = H(i,j) + H(j,i)$
- · cover time: expected number of steps to reach every node
- mixing time  $\tau(\epsilon)$ : a measure of how fast the random walk approaches its stationary distribution

$$\tau(\epsilon) = \min\{t \mid d(t) \le \epsilon\}$$

where

$$d(t) = \max_i ||\mathbf{p}^t(i,\cdot) - \pi|| = \max_i \left\{ \sum_j |\mathbf{p}^t(i,j) - \pi_j| 
ight\}$$

## random walks vs. spectral analysis

• consider the normalized laplacian  $L = I - D^{-1/2}AD^{-1/2}$ 

$$L\mathbf{u} = \lambda \mathbf{u}$$

$$(I - D^{-1/2}AD^{-1/2})\mathbf{u} = \lambda \mathbf{u}$$

$$(D - A)\mathbf{u} = \lambda D\mathbf{u}$$

$$D\mathbf{u} = A\mathbf{u} + \lambda D\mathbf{u}$$

$$(1 - \lambda)\mathbf{u} = D^{-1}A\mathbf{u}$$

$$\mu \mathbf{u} = P\mathbf{u}$$

- (λ, u) is an eigenvalue-eigenvector pair for L if and only if
   (1 λ, u) is an eigenvalue-eigenvector pair for P
- the eigenvector with smallest eigenvalue for L is the eigenvector with largest eigenvalue for P

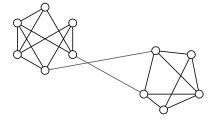

## random walks vs. spectral analysis

- stochastic matrix P, describing the random walk
- eigenvalues:  $-1 < \mu_n \le ... \le \mu_2 < \mu_1 = 1$
- spectral gap:  $\gamma_* = 1 \mu_2 = \lambda_2$
- relaxation time:  $\tau_* = \frac{1}{\gamma_*}$
- theorem: for an aperiodic, irreducible, and reversible random walk, and any  $\epsilon$

$$( au_* - 1)\log\left(rac{1}{2\epsilon}
ight) \leq au(\epsilon) \leq au_*\log\left(rac{1}{2\epsilon\sqrt{\pi_{\mathsf{min}}}}
ight)$$

## random walks vs. spectral analysis

intuition: fast mixing related to graph being an expander

small spectral gap  $\Leftrightarrow$  large mixing time  $\Leftrightarrow$  bottlenecks  $\Leftrightarrow$   $\Leftrightarrow$  clusters  $\Leftrightarrow$  low conductance  $\Leftrightarrow$  small  $\lambda_2$ 

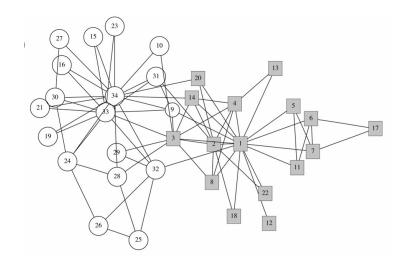

# graph partitioning

## graph partitioning and community detection

#### motivation

- knowledge discovery
- partition the web into sets of related pages (web graph)
- find groups of scientists who collaborate with each other (co-authorship graph)
- find groups of related queries submitted in a search engine (query graph)
- performance
- partition the nodes of a large social network into different machines so that, to a large extent, friends are in the same machine (social networks)

# graph partitioning

(Zachary's karate-club network, figure from [Newman and Girvan, 2004])

# basic spectral-partition algorithm

- 1. form normalized Laplacian  $L' = I D^{-1/2}AD^{-1/2}$
- **2.** compute eigenvector  $\mathbf{x}_2$  (Fielder vector)
- 3. order vertices according their coefficient value on x2
- 4. consider only sweeping cuts: splits that respect the order
- **5.** take the sweeping cut S that minimizes  $\phi(S)$

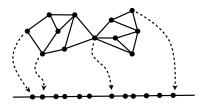

theorem: the basic spectral-partition algorithm finds a cut S such that  $\phi(S) \leq 2\sqrt{\phi(G)}$ 

proof: by Cheeger inequality

$$\phi(S) \leq \sqrt{2 \cdot \lambda_2} \leq \sqrt{2 \cdot 2 \cdot \phi(G)}$$

# spectral partitioning rules

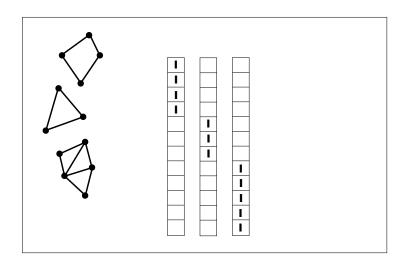

- **1.** conductance: find the partition that minimizes  $\phi(G)$
- 2. bisection: split in two equal parts
- 3. sign: separate positive and negative values
- 4. gap: separate according to the largest gap

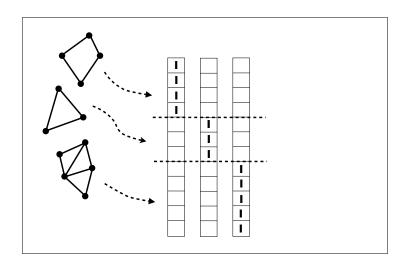

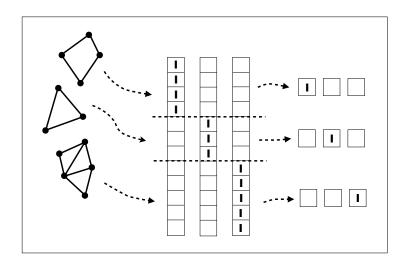

# other common spectral-partitioning algorithms

- utilize more eigenvectors than just the Fielder vector use k eigenvectors
- 2. different versions of the Laplacian matrix

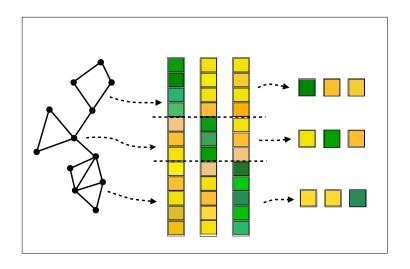

- ideal scenario: the graph consists of k disconnected components (perfect clusters)
- then: eigenvalue 0 of the Laplacian has multplicity k
  the eigenspace of eigenvalue 0 is spanned by indicator
  vectors of the graph components

- robustness under perturbations: if the graph has less well-separated components the previous structure holds approximately
- clustering of Euclidean points can be used to separate the components

## laplacian matrices

- normalized laplacian:  $L = I D^{-1/2}AD^{-1/2}$
- unormalized laplacian:  $L_{\mu} = D A$
- normalized "random-walk" laplacian:  $L_{rw} = I D^{-1}A$

## all laplacian matrices are related

- unormalized Laplacian:  $\lambda_2 = \min_{\substack{||\mathbf{x}||=1 \\ \mathbf{x}^T \mathbf{u}_1 = 0}} \sum_{(i,j) \in E} (x_i x_j)^2$
- normalized Laplacian:

$$\lambda_2 = \min_{\substack{||\mathbf{x}||=1\\\mathbf{x}^T\mathbf{u}_1=0}} \sum_{(i,j)\in E} (\frac{x_i}{\sqrt{d_i}} - \frac{x_j}{\sqrt{d_j}})^2$$

- (λ, u) is an eigenvalue/vector of L<sub>rw</sub> if and only if
   (λ, D<sup>1/2</sup> u) is an eigenvalue/vector of L
- (λ, u) is an eigenvalue/vector of L<sub>rw</sub> if and only if
   (λ, u) solve the generalized eigen-problem L<sub>u</sub> u = λ D u

# algorithm 1: unormalized spectral clustering

input graph adjacency matrix A, number k

- 1. form diagonal matrix D
- 2. form unormalized Laplacian L = D A
- 3. compute the first k eigenvectors  $u_1, \ldots, u_k$  of L
- 4. form matrix  $U \in \mathbb{R}^{n \times k}$  with columns  $u_1, \dots, u_k$
- 5. consider the *i*-th row of *U* as point  $y_i \in \mathbb{R}^k$ , i = 1, ..., n,
- 6. cluster the points  $\{y_i\}_{i=1,...,n}$  into clusters  $C_1,\ldots,C_k$  e.g., with k-means clustering

output clusters  $A_1, \ldots, A_k$  with  $A_i = \{j \mid y_j \in C_i\}$ 

# algorithm 2: normalized spectral clustering

[Shi and Malik, 2000]

input graph adjacency matrix A, number k

- 1. form diagonal matrix D
- 2. form unormalized Laplacian L = D A
- 3. compute the first k eigenvectors  $u_1, \ldots, u_k$  of the generalized eigenproblem  $L \mathbf{u} = \lambda D \mathbf{u}$  (eigvctrs of  $L_{rw}$ )
- 4. form matrix  $U \in \mathbb{R}^{n \times k}$  with columns  $u_1, \dots, u_k$
- 5. consider the *i*-th row of *U* as point  $y_i \in \mathbb{R}^k$ , i = 1, ..., n,
- 6. cluster the points  $\{y_i\}_{i=1,\dots,n}$  into clusters  $C_1,\dots,C_k$  e.g., with k-means clustering

output clusters  $A_1, \ldots, A_k$  with  $A_i = \{j \mid y_i \in C_i\}$ 

# algorithm 3: normalized spectral clustering

[Ng et al., 2001]

input graph adjacency matrix A, number k

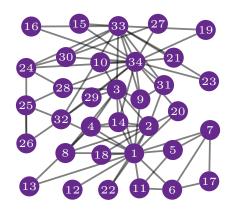

- 1. form diagonal matrix D
- 2. form normalized Laplacian  $L' = I D^{-1/2}AD^{-1/2}$
- 3. compute the first k eigenvectors  $u_1, \ldots, u_k$  of L'
- 4. form matrix  $U \in \mathbb{R}^{n \times k}$  with columns  $u_1, \dots, u_k$
- 5. normalize U so that rows have norm 1
- 6. consider the *i*-th row of *U* as point  $y_i \in \mathbb{R}^k$ , i = 1, ..., n,
- 7. cluster the points  $\{y_i\}_{i=1,...,n}$  into clusters  $C_1,\ldots,C_k$  e.g., with k-means clustering

output clusters  $A_1, \ldots, A_k$  with  $A_i = \{j \mid y_j \in C_i\}$ 

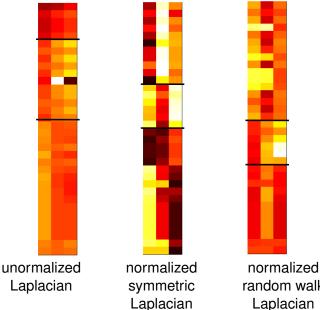

## notes on the spectral algorithms

- quite similar except for using different Laplacians
- can be used to cluster any type of data, not just graphs form all-pairs similarity matrix and use as adjacency matrix
- computation of the first eigenvectors of sparse matrices can be done efficiently using the Lanczos method

# Zachary's karate-club network

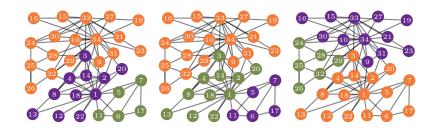

# **Zachary's karate-club network**

random walk Laplacian

# Zachary's karate-club network

unormalized Laplacian normalized symmetric Laplacian

normalized random walk Laplacian

# which Laplacian to use?

#### [von Luxburg, 2007]

- when graph vertices have about the same degree all laplacians are about the same
- for skewed degree distributions normalized laplacians tend to perform better
- normalized laplacians are associated with conductance, which is a good objective (conductance involves vol(S) rather than |S| and captures better the community structure)

# modularity

- cut measures (conductance) useful to find one component
- how to find many components?
- related question: what is the optimal number of partitions?
- modularity has been used to answer those questions [Newman and Girvan, 2004]
- originally developed to find the optimal number of partitions in hierarchical graph partitioning

## modularity

 intuition: compare actual subgraph density with expected subgraph density, if vertices were attached regardless of community structure

$$Q = \frac{1}{2m} \sum_{ij} (A_{ij} - P_{ij}) \delta(C_i, C_j)$$

$$= \frac{1}{2m} \sum_{ij} (A_{ij} - \frac{d_i d_j}{2m}) \delta(C_i, C_j)$$

$$= \sum_{c} \left[ \frac{m_c}{2m} - \left( \frac{d_c}{2m} \right)^2 \right]$$

$$P_{ij} = 2mp_ip_j = 2m(d_i/2m)(d_j/2m) = (d_id_j/2m)$$
  
 $m_c$ : edges within cluster  $c$   
 $d_c$ : total degree of cluster  $c$ 

## values of modularity

- 0 random structure; 1 strong community structure;
   [0.3..0.7]; typical good structure; can be negative, too
- Q measure is not monotone with k

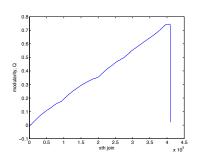

FIG. 1: The modularity Q over the course of the algorithm (the x axis shows the number of joins). Its maximum value is Q = 0.745, where the partition consists of 1684 communities.

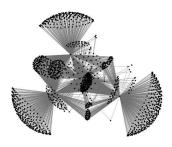

FIG. 2: A visualization of the community structure at maximum modularity. Note that the some major communities have a large number of "satellite" communities connected only to them (top, lower left, lower right). Also, some pairs of major communities have sets of smaller communities that act as "bridges" between them (e.g., between the lower left and lower right, near the center).

(figures from [Clauset et al., 2004])

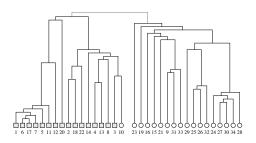

# optimizing modularity

- problem: find the partitioning that optimizes modularity
- NP-hard problem [Brandes et al., 2006]
- top-down approaches [Newman and Girvan, 2004]
- spectral approaches [Smyth and White, 2005]
- mathematical-programming [Agarwal and Kempe, 2008]

# top-down algorithms for optimizing modularity

#### [Newman and Girvan, 2004]

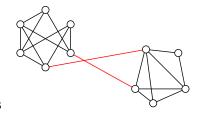

- a set of algorithms based on removing edges from the graph, one at a time
- the graph gets progressively disconnected, creating a hierarchy of communities

(figure from [Newman, 2004])

# top-down algorithms

select edge to remove based on "betweenness"

#### three definitions

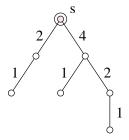

- shortest-path betweenness: number of shortest paths that the edge belongs to
- random-walk betweenness: expected number of paths for a random walk from u to v
- current-flow betweenness: resistance derived from considering the graph as an electric circuit

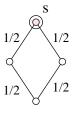

## top-down algorithms

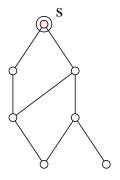

#### general scheme

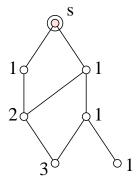

- 1. Top-Down
- compute betweenness value of all edges
- 3. remove the edge with the highest betweenness
- 4. recompute betweenness value of all remaining edges
- 5. repeat until no edges left

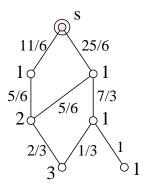

- how to compute shortest-path betweenness?
- BFS from each vertex
- leads to O(mn) for all edge betweenness
- OK if there are single paths to all vertices

overall time of TOPDOWN is  $O(m^2n)$ 

#### random-walk betweenness

- stochastic matrix of random walk is  $P = D^{-1} A$
- s is the vector with 1 at position s and 0 elsewhere
- probability distribution over vertices at time n is s P<sup>n</sup>
- expected number of visits at each vertex given by

$$\sum_{n} \mathbf{s} P^{n} = \mathbf{s} (1 - P)^{-1}$$

$$c_u = E[\# \text{ times passing from } u \text{ to } v] = \left[\mathbf{s} (1 - P)^{-1}\right]_u \frac{1}{d_u}$$

$$\mathbf{c} = \mathbf{s} (1 - P)^{-1} D^{-1} = \mathbf{s} (D - A)^{-1}$$

• define random-walk betweenness at (u, v) as  $|c_u - c_v|$ 

#### random-walk betweenness

- random-walk betweenness at (u, v) is  $|c_u c_v|$ with  $\mathbf{c} = \mathbf{s} (D - A)^{-1}$
- one matrix inversion  $O(n^3)$
- in total  $O(n^3m)$  time with recalculation
- not scalable
- current-flow betweenness is equivalent!

[Newman and Girvan, 2004] recommend shortest-path betweenness

# other modularity-based algorithms

spectral approach [Smyth and White, 2005]

$$Q = \sum_{c=1}^{k} \left[ \frac{m_c}{2m} - \left( \frac{d_c}{2m} \right)^2 \right] \propto \sum_{c=1}^{k} \left[ (2m) m_c - d_c^2 \right]$$

$$= \sum_{c=1}^{k} \left[ (2m) \sum_{i,j=1}^{n} w_{ij} x_{ic} x_{jc} - \left( \sum_{i=1}^{n} d_i x_{ic} \right)^2 \right]$$

$$= \sum_{c=1}^{k} \left[ (2m) \mathbf{x}_c^T W \mathbf{x}_c - \mathbf{x}_c^T D \mathbf{x}_c \right]$$

$$= \operatorname{tr}(X^T (W' - D) X)$$

where  $X = [\mathbf{x}_1 \dots \mathbf{x}_k] = [x_{ic}]$  point-cluster assignment matrix

# spectral-based modularity optimization

maximize 
$$\operatorname{tr}(X^T(W'-D)X)$$
  
such that  $X$  is an assignment matrix

#### solution:

$$L_Q X = X \Lambda$$

where  $L_Q = W' - D$ , Q-Laplacian

- standard eigenvalue problem
- but solution is fractional, we want integral
- treat rows of X as vectors and cluster graph vertices using k-means
- [Smyth and White, 2005] propose two algorithms, based on this idea

# spectral-based modularity optimization

spectral algorithms perform almost as good as the agglomerative, but they are more efficient

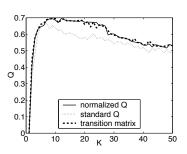

Figure 3: Q versus k for the WordNet data.

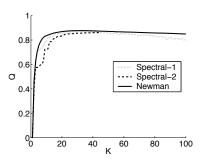

Figure 7: Q versus k for NIPS coauthorship data.

[Smyth and White, 2005]

# other modularity-based algorithms

mathematical programming [Agarwal and Kempe, 2008]

$$Q \propto \sum_{i,j=1}^n B_{ij}(1-x_{ij})$$

where

$$x_{ij} = \begin{cases} 0 & \text{if } i \text{ and } j \text{ get assigned to the same cluster} \\ 1 & \text{otherwise} \end{cases}$$

it should be

$$x_{ik} \le x_{ij} + x_{jk}$$
 for all vertices  $i, j, k$ 

solve the integer program with triangle inequality constraints

# mathematical-programming approach for modularity optimization

#### [Agarwal and Kempe, 2008]

- integer program is NP-hard
- relax integrality constraints
   replace x<sub>ij</sub> ∈ {0, 1} with 0 ≤ x<sub>ij</sub> ≤ 1
- corresponding linear program can be solved in polynomial time
- solve linear program and round the fractional solution
- place in the same cluster vertices i and j if x<sub>ij</sub> is small (pivot algorithm [Ailon et al., 2008])

#### **Results**

**Table 2.** The modularity obtained by many of the previously published methods and by the methods introduced in this paper, along with the upper bound.

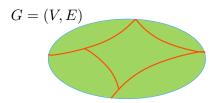

(table from [Agarwal and Kempe, 2008])

# need for scalable algorithms

- spectral, agglomerative, LP-based algorithms
- not scalable to very large graphs
- handle datasets with billions of vertices and edges
  - facebook: ~ 1 billion users with avg degree 130
  - twitter: > 1.5 billion social relations
  - google: web graph more than a trillion edges (2011)
- design algorithms for streaming scenarios
  - real-time story identification using twitter posts
  - election trends, twitter as election barometer

# graph partitioning

- graph partitioning is a way to split the graph vertices in multiple machines
- graph partitioning objectives guarantee low communication overhead among different machines
- additionally balanced partitioning is desirable

• each partition contains  $\approx n/k$  vertices

# off-line k-way graph partitioning

#### METIS algorithm [Karypis and Kumar, 1998]

- popular family of algorithms and software
- multilevel algorithm
- coarsening phase in which the size of the graph is successively decreased
- followed by bisection (based on spectral)
- followed by uncoarsening phase in which the bisection is successively refined and projected to larger graphs

#### summary

- spectral analysis reveals structural properties of a graph
- used for graph partitioning, but also for other problems
- well-studied area, many results and techniques
- for graph partitioning and community detection many other methods are available
